

Harmful Algal Blooms (HABs) 4 Validation

Validation

The background image shows a massive, churning wave of bright green water, characteristic of a harmful algal bloom. The water is turbulent, with white foam and spray visible as the wave breaks. The color is a vibrant, almost neon green, contrasting sharply with the blue of the sky and the darker green of the water in the foreground.

What is it?

Why validate

When to validate

How to validate, which leads to Where

Microcystis, Credit: Thomas Archer,
Columbus Ohio

What is Validation

Quantitative: algorithm gives quantity
how accurate is the quantity?

Qualitative: algorithm indicates presence/absence or
type of bloom
is it reliable?

Why Validate

Robustness: does it hold up for various images (atmos. error etc.)

Reproducibility: does it apply over multiple years, regions, satellites

Usability: is it useful enough for the applications

Accuracy in algorithm

Is it useful

- false positives (type 1 error); the HAB actually is there

- false negatives (type 2 error); the HAB is NOT there

When to Validate

Application of field algorithm to satellite

Use by managers

Use in time series or climatological analysis

How to Validate

Determine whether algorithm is quantitative or qualitative

Determine how the algorithm will be used

Finding a bloom for manager is different than mapping extent for ecological study.

Quantity or presence?

B A

Boat Wake

Cyano and dinoflagellate blooms are quite patchy

400 m

Why are HABs difficult to map? they are patchy.
An extremely dense patch of *Karenia brevis* (toxic dinoflagellate)

unusually intense
“red tide”

Patchiness even with best observations

Baltic, 2005, cyanobacteria,
commonly estimated from
satellite.

This bloom missed west Öland
beaches, Tourism crisis,
source E. Graneli

Vertical patchiness:
Thin Layer issue, especially *Dinophysis*,
Resolvable with absorption measurements, provided the layer
can be found. Major issue in European coastal waters

Gentien et al., 2005

One validation, quantity and presence

Bloom found and confirmed with data provides quantity.

This bloom is a problem for qualitative validation.

Why?

Validation

99 samples in one bloom. All correct

One sample outside bloom. Incorrect.

Pixel math says 99% accuracy

Reality: 50% accuracy (one bloom right, one wrong)

Validation concept

Quantitative is for quantity, typically pixel based, e.g., chlorophyll validation.

Qualitative is for classification, draw on land-cover techniques

This may be pixel based (e.g. bloom types).

However, HAB application is usually “bloom presence” (where is the bloom?) so “feature” based.

Difference of same day samples < 1 km apart,

K. Brevis Florida

Tomlinson et al. 2009

**What is the correct validation?
(Rhetorical question)**

**19% of same km pairs have
Both “hazardous” and “absent”**

Patchiness issue

B A

Boat Wake

Cyano and dinoflagellate blooms are quite patchy

400 m

Uncertainty is not error. (vertical bar is counting error, not spatial error)

Satellite against field cell counts

Qualitative sampling

Blooms are spatially and temporally autocorrelated.

Spatial autocorrelation:

adjacent cells are likely same

Temporal autocorrelation:

blooms last for weeks

What to do about spatial autocorrelation

Land cover community uses “stratified random sampling”
Stratify by cover type, and randomly select.

This image does NOT show stratified
Random sampling.

Problem in marine environment:
Logistics, our study areas are remote and
don't stay around for months or years.

What to do about temporal autocorrelation

Must sample at the scale of “non-correlation”.

No more frequent than weekly. (Scale of fronts in mid-latitudes)

What difference does it make?

If you are right, you are always right

If you are wrong, you are always wrong

What to do about temporal autocorrelation

This image could have 94% accuracy. 31 of 34 samples correctly identified the bloom.

What is wrong with this accuracy?

The satellite found 1 bloom, not 31 blooms.

When used to support users, manual evaluation of imagery is common.

In this image, both red and yellow areas passed the anomaly test.

However, the red area was identified from previous imagery.

The yellow area was interpreted as non-bloom from knowledge of the region. (Validated later)

Automated analysis would say that both are *Karenia*.

Patchiness causes changes in accuracy with change in resolution

Patchiness, and lack of resolution (clouds, satellite resolution). Stumpf et al., JMS, 2008

County-wide Forecast of moderate/high respiratory impact

Correct County-wide (at least one beach)	73%
Correct against individual reports from 6 beaches	21%

Credit: Paul Schmidt

Locating a HAB, sampling problem (Florida)

Even an excellent program has limited resolution

A week of sampling in FL, source: FWRI database, research.myfwc.com

Oversimplified: If you need data every day at every 1 km, then you will need to sample at least 1 day at every 1 km.

Stumpf et al., JMS, 2009

Other methods can be used for validation

Toxin measurements in water or shellfish.

Sometimes fishkills

Not discolored water.

Here are images, design a sampling plan
